Management Evaluation

Current Postseason Population Management Objective: 500

2012 Postseason Population Estimate: ~550

2013 Proposed Postseason Population Estimate: ~550

Herd Unit Issues. Most sheep in this herd unit are found in the Absaroka Mountains, although a small number (currently less than 50) occupy the Beartooth Mountains year-round. Some Absaroka Mountain sheep from the northern portion of the herd unit migrate into Montana, where they are subjected to hunting seasons there (currently an unlimited season with a harvest quota of 2). These sheep often end up wintering in the Wyoming portion of the Beartooth Mountains. In addition, perhaps 10%-15% of the sheep in this herd unit reside (some seasonally, some year-round) in Yellowstone National Park (YNP). Both of these factors (Montana harvest and sheep unavailable for harvest in YNP) are taken into account when managing this herd. Periodic fixed-wing trend counts (and more recently helicopter classification/trend surveys) during summer have been used to assess population performance. Summer surveys are done because many sheep migrate into Montana to winter, and surveys were designed to more closely monitor sheep while on Wyoming summer ranges. Classifications collected mid-summer are useful in tracking ram:ewe ratios, but allow little understanding of lamb survival as they are conducted so early in the year.

Weather. Weather conditions during the 2012 biological year were conducive to bighorn sheep reproduction and survival throughout the Absaroka Mountains, with below normal snow water equivalents (a reflection of winter severity), but normal to near normal precipitation to promote forage growth.

Habitat. No habitat monitoring data is collected in this herd unit. Unless spring snow accumulations increase dramatically (as they did in several areas of the Absaroka Mountains in spring 2011), survival and lamb production should be good in 2013.

Field Data. Classification samples from recent surveys reflect good lamb:ewe (51:100 – 65:100) and ram:ewe (42:100 – 56:100) ratios in most years surveyed (6 surveys over the last 10 years). Poor lamb:ewe ratios as seen in 2009 (32:100) do occasionally occur and can affect ram recruitment. Recent trend counts (401 sheep in 2006, 409 in 2009, 390 in 2011) also provide support that this herd is probably near the objective of 500 sheep.

Harvest Data. In 2012, 20 hunters took 15 rams for a success rate of 75.0%, which is among the better years seen since permits were increased to 20 in 2007. The average age of rams killed in 2012 was 7.4 years old, with 40.0% of the rams killed being 8 years old and older. No rams less than $\frac{3}{4}$ curl were killed in 2012. Although the harvest quota in Montana Hun District 502 is only 2 rams, 4 rams were taken in 2012.

Population. The “Time Specific Juvenile – Constant Adult Mortality Rate” (TSJCA) spreadsheet model was chosen to use for the post season population estimate of this herd. Although this model did not have the lowest relative AIC, the population estimate appears to be the most reasonable. The earlier trend projected by the model (early 1990s – early 2000s) is not felt to be entirely accurate, but estimates in the recent past appear reasonable. The postseason 2012 population is estimated to be approximately 550 sheep. Efforts will continue to improve this model and improve reliability.

Management Summary. All indicators show good population performance, and an acceptable presence of mature rams. Therefore license numbers will remain at 20 for the 2013 season. This should result in a postseason 2013 population of approximately 550 sheep.

Management Evaluation

Current Postseason Population Management Objective: 750

2012 Postseason Population Estimate: ~675

2013 Proposed Postseason Population Estimate: ~650

Herd Unit Issues. The Trout Peak Herd Unit possesses some of the most difficult terrain in Wyoming, which is partially responsible for the wide variation in hunter statistics for which this herd is famous. A small percentage of sheep (presumably less than 10%) reside within Yellowstone National Park. Sheep can be found on low elevation winter ranges along the North Fork of the Shoshone River, but also occupy high elevation ranges throughout the hunt area.

Weather. Weather conditions during the 2012 biological year were conducive to bighorn sheep reproduction and survival throughout the Absaroka Mountains, with below normal snow water equivalents (a reflection of winter severity), but normal to near normal precipitation to promote forage growth.

Habitat. No habitat monitoring data is collected in this herd unit. Unless spring snow accumulations increase dramatically (as they did in several areas of the Absaroka Mountains in spring 2011), survival and lamb production should be good in 2013.

Field Data. Seven surveys have been conducted over the last 10 years, resulted in samples ranging from 117 to 480 classified sheep. Lamb:ewe ratios have ranged from 15:100 to 31:100 over this time, while ram:ewe ratios have varied from 30:100 to 67:100. The most recent survey in 2011 resulted in 465 sheep observed, representing one of the higher sample sizes obtained, even though the western portion of the hunt area was not surveyed. The lamb:ewe ratio for this sample was 26:100, which is slightly below the recent average. The ram:ewe ratio was 41:100 which is about average.

Harvest Data. In 2012, 24 hunters took 20 rams for a success rate of 83%, which is among the better years experienced by this herd unit. The average age of rams killed in 2012 was 8.6 years old, with 68.4% of the rams killed being 8 years old and older, which was not predicted, but is not entirely surprising as this herd has traditionally exhibited large fluctuations in harvest statistics, primarily a result of it being the most difficult terrain in which to hunt sheep in Wyoming. One ram less than $\frac{3}{4}$ curl was killed in 2012.

All of these indicators, plus good lamb:ewe and ram:ewe ratios from recent surveys, indicate good population performance, and an acceptable presence of mature rams.

Population . The “Time Specific Juvenile – Constant Adult Mortality Rate” (TSJCA) spreadsheet model was chosen to use for the post season population estimate of this herd. Although this model did not have the lowest relative AIC, the population estimate and trend appears to be very reasonable. The postseason 2012 population is estimated to be 675 sheep. Efforts will continue to improve this model and improve reliability.

Management Summary. Since adopting the any ram regulation in 2004, this herd unit has exhibited some of the variation in harvest parameters for which it has always been famous. When averaged over the last 8 years, however, harvest parameters are within desirable ranges. Therefore permit levels will be set at 24 licenses for the 2013 season (25 with the additional nonresident hunter needed to attain a statewide 75:25 split between residents and nonresidents). The postseason 2013 population is estimated to be approximately 650 sheep.

Harvest parameters for the Trout Peak Bighorn Sheep Herd, 1978-2012.

	1978-96	1997-2002	2003	2004-2011*	2012*

Management Evaluation

Current Postseason Population Management Objective: 1,000

2012 Postseason Population Estimate: ~1,025

2013 Proposed Postseason Population Estimate: ~950

Herd Unit Issues. The Wapiti Ridge Herd Unit consists of sheep that occupy low elevation winter ranges along the North and South Forks of the Shoshone River, but also occupy high elevation ranges throughout the hunt area. A small percentage of sheep (presumably less than 10%) reside within Yellowstone National Park.

Weather. Weather conditions during the 2012 biological year were conducive to bighorn sheep reproduction and survival throughout the Absaroka Mountains, with below normal snow water equivalents (a reflection of winter severity), but normal to near normal precipitation to promote forage growth.

Habitat. No habitat monitoring data is collected in this herd unit. Unless spring snow accumulations increase dramatically (as they did in several areas of the Absaroka Mountains in spring 2011), survival and lamb production should be good in 2013. This herd unit likely suffered impacts from the above normal snowfall received during the spring of 2011.

Field Data. Eight surveys have been conducted over the last 10 years, resulted in samples ranging from 315 to 914 classified sheep. Lamb:ewe ratios have ranged from 12:100 to 37:100 over this time, while ram:ewe ratios have varied from 32:100 to 46:100. The most recent survey in 2011 resulted in 661 sheep observed, a lamb:ewe ratio of 12:100 (which is well below the recent average), and a ram:ewe ratio of 36:100, which is about average for this herd unit.

Harvest Data. In 2012, 46 hunters took 38 rams for a success rate of 83%, which is about average for this herd unit. The average age of rams killed in 2012 was 6.8 years old, with 31.6% of the rams killed being 8 years old and older. Four rams less than $\frac{3}{4}$ curl were killed in 2012. Hunter effort was 11.5 days per ram harvested in 2012, which is higher (although not substantially) than most years. These figures represent a return to levels that triggered permit reductions in the early 2000s.

Population. The “Time Specific Juvenile – Constant Adult Mortality Rate” (TSJCA) spreadsheet model was chosen to use for the post season population estimate of this herd. Although this model did not have the lowest relative AIC, the population estimate appears to be reasonable. The rather steep decline produced by the model however, is not believed to entirely realistic. The postseason 2012 population is estimated to be 1,025 sheep. Efforts will continue to improve this model and improve reliability.

The effects of the very poor lamb crop of 2005 (17 lambs:110 ewes) was felt in 2012, and should continue to be felt again this year, as this cohort should be 8 year old rams in 2013. This may be offset somewhat by a much better lamb:ewe ratio in 2006 (37:100). However, another worrisome factor is the number of pickup heads registered in 2011 (n=21) and 2012 (n=24). These numbers represent an increase of 69% and 94% over the previous 10-year average number of pickup heads per year. The 2010-2011 winter obviously had impacts on this population, as evidenced by the lamb:ewe ratio of 12:100 seen in postseason 2011 surveys.

Management Summary. With the extremely poor lamb production experienced recently, it is likely that the availability of rams will decline in this herd unit in coming years as lambs from these cohorts enter mature ram age classes. Further permit reductions may be necessary in the near future to preserve or improve ram hunting opportunities. Harvest statistics should be monitored closely to determine if such a situation is developing. License numbers will be reduced to 40 for the 2013 season. The postseason 2013 population is estimated to be approximately 950 sheep.

Harvest parameters for the Wapiti Ridge Bighorn Sheep Herd Unit, 1978-2012.

Management Evaluation

Current Postseason Population Management Objective: 900

2012 Postseason Population Estimate: ~850

2013 Proposed Postseason Population Estimate: ~800

Herd Unit Issues. The Younts Peak Herd Unit is characterized by sheep that live at extremely high elevation year-round. This subjects many of them to occasionally heavy winter losses, which occurred in 1995, 1996, and 2010. Anthropogenic factors have limited impacts on this population since most of the area is wilderness and access to this area is difficult. No human development (oil/gas, mining, housing) currently affect this population or their habitats.

Weather. Weather conditions during the 2012 biological year were conducive to bighorn sheep reproduction and survival throughout the Absaroka Mountains, with below normal snow water equivalents (a reflection of winter severity), but normal to near normal precipitation to promote forage growth.

Habitat. No habitat monitoring data is collected in this herd unit. Unless spring snow accumulations increase dramatically (as they did in this herd unit in spring 2011), survival and lamb production should be good in 2013.

Field Data. Five surveys have been conducted over the last 10 years, resulted in samples ranging from 233 to 567 classified sheep. Lamb:ewe ratios have ranged from 17:100 to 36:100 over this time, although 3 of these surveys produced lamb:ewe ratios of 17:100, 21:100, and 22:100. Ram:ewe ratios have varied from 30:100 to 54:100. The most recent survey in 2011 resulted in 505 sheep observed, a lamb:ewe ratio of 17:100 (which is well below the recent average), and a ram:ewe ratio of 48:100, which is slightly below average for this herd unit.

Harvest Data. In 2012, 31 hunters took 18 rams for a success rate of 58%, which is the lowest seen in this herd unit since 1995, when this herd last experienced heavy winter-related mortality. The average age of rams killed in 2012 was 7.2 years old, with only 22.2% of the rams killed being 8 years old and older. One ram less than $\frac{3}{4}$ curl was killed in 2012. Hunter effort was 12.4 days per ram harvested in 2012, and 14.8 days per ram harvested in 2011, both of which represent some of the highest effort values in this herd

unit, and again echo back to the early 1990s. These figures represent a return to levels that triggered permit reductions in during that time.

Population. The “Time Specific Juvenile – Constant Adult Mortality Rate” (TSJCA) spreadsheet model was chosen to use for the post season population estimate of this herd. Although this model did not have the lowest relative AIC, the population trend is much more reasonable than other models. The postseason 2012 population is estimated to be 850 sheep. Efforts will continue to improve this model.

Similar to Area 3, the number of pickup heads registered recently has supported concerns over the impacts of the 2010-2011 winter. In 2011, 16 pickup heads were registered, representing 167% of the previous 10-year average. Although fewer, the 8 pickup heads registered in 2012 still represent a 33% increase over the previous 10-year average. When Snow Water Equivalent (SWE) is plotted for the Younts Peak SnoTel site, the 2010-2011 winter had well above normal accumulations of snow. Previous years with high SWE levels (1985-86, 1995-96, 1996-97) also began accumulating snow earlier in the winter. The 2010-2011 winter was essentially normal for most of the winter, but quickly began to accumulate and retain above far above average levels of snow in April, May, and June. This was not true for the winter of 1994-95, however, which was only slightly higher than normal in May and June with respect to SWE. Snow (snow depth only measured since 1998) is usually gone by June, but in June 2011 there was still 20 inches at the Younts Peak SnoTel site. The 2010-2011 winter obviously had impacts on this population, as evidenced by the lamb:ewe ratio of 12:100 seen in postseason 2011 surveys.

Management Summary. With the extremely poor lamb production experienced recently, it is likely that the availability of rams will not recover rapidly in this herd unit in coming years as lambs from these cohorts enter mature ram age classes. Maintenance of reduced ram hunting opportunities may be necessary in the near future to preserve or improve ram hunting opportunities. Ram:ewe ratios, average age of harvested rams, and the percentage of rams at least 8 years of age and older should be monitored closely to determine if such a situation is developing. License numbers will be reduced to 20 for the 2013 season. The postseason 2013 population is estimated to be approximately 800 sheep.

Management Evaluation

Current Postseason Population Management Objective: 1,360

Management Strategy: Avg. age of harvested rams from 6-8 years

2012 Postseason Population Estimate: 1,400

2013 Proposed Postseason Population Estimate: 1,400

Herd Unit Issues. The management strategy for this sheep herd is to maintain an average age of harvested rams between 6-8 years old, along with a hunter success of >80%. The herd objective and management strategy will be revised in 2013. Using a population objective and model estimate for this sheep herd has always been questionable. Field personnel feel and have continually used hunter success and average age of harvested rams as the main gauge for setting seasons. Lamb ratios are also monitored closely to anticipate potential changes in age classes of rams. Relative densities of sheep vary within the herd unit. In hunt area 5, much of the occupied habitat occurs at alpine elevations, whereas in hunt area 22, a number of sheep occupy the badlands north of the Wind River, with some sheep spending time on irrigated meadows on the Fish Ranch. In the Owl Creek Mountain's of the WRIR, bighorn sheep are found year round above 9,500'. For the most part, this sheep herd has remained mostly stable the past 7 years, with a slight decline starting to be noticed after the 2010/11 winter, when it appeared some

winter die-off had occurred. In fact, since January 2011, 104 ram pickup heads have been registered, which is about 150% above normal.

Weather. The winters of 2011/12 and 2012/13 were mild with low snowpack resulting in mostly good over winter survival. However, the winter of 2010/11 appeared to have been severe enough to cause some die-off as well as reduced lamb production. The extreme dry conditions of 2012 resulted in some changes to distribution of sheep on their summer range, likely because of reduced forage production and condition.

Habitat. Habitat conditions for the most part are considered good to excellent in this herd unit. The Little Venus fire in 2006, and the Norton Point fire in 2011 improved overall forage availability and production in hunt area 5. The drought conditions in 2012 did cause lower than normal forage production.

Field Data. Aerial classifications surveys are used in obtaining post-season lamb and ram ratio for this sheep herd. On average about 400-800 sheep are classified annually. Lamb:ewe ratios for the herd have remained favorable the past 10 years, with an average ratio of 30:100. Ram:ewe ratios typically exceed 50:100. In 2011 lamb ratios were only 16:100, the lowest in 10 years. This reduced lamb ratio, along with the current die-off may result in a decline in hunting opportunity in the future. A late winter flight in mid-April 2013 resulted in 350 sheep being observed, about 50 less than in January 2013, but with a similar number of rams being observed and only a slight decline in the lamb ratio. The decline in the number of sheep being observed between the January and April flight was not significant enough to warrant any changes to either the current hunting season structure or to cause any heightened concern about a major die-off.

Harvest Data. Annual hunter numbers in this herd unit have fluctuated since 2007, but on average area 5 has about 71 hunters, area 22 about 2-3 hunters, and the WRIR about 10 hunters. Annual harvest since 2007 has been about 75 rams for the herd unit, with roughly 65 from area 5, 1-2 from area 22, and about 6-8 from the WRIR. Hunter success is typically about 85-90%, with hunter effort at about 6-8 days/animal harvested. In hunt area 5 since 2007, the age of harvested rams has averaged about 7.7 years. The percent of harvested rams \geq 8 years of age has averaged about 45%. The 2012 ewe harvest in area 5 showed 15 ewes being harvested for a hunter success of 75%. This was the first year for ewe hunting in any Wyoming sheep hunt area. Because of this, we would like to keep using these ewe hunts to not only manage ewe populations on winter ranges, but to also promote public awareness and acceptance of these ewe hunts.

Population. The constant juvenile & constant adult survival (CJ, CA) spreadsheet model was chosen to represent this herd because it reflects a good recent year trend (2011-2013) in the population. However, the long-term trend contradicts field personnel perceptions, harvest data and classification sample sizes, which indicate a mostly stable population for at least the past 10 years. Because of this, the overall model is considered mostly unreliable. The model supported an AIC value of 155, which was not the lowest of the three models. The model is considered a poor representation of the herd.

Management Summary

The low lamb ratios in 2011 (16:100) and the recent ram pickup heads (n=104) possess some concerns for this sheep herd. Because of this, we will keep license quotas similar to 2012, with

only a drop of one license for the Type 1 quota in area 5. For the Type 6 season in area 5, we will reduce this quota by 12 licenses, but include the Jack Creek and Pickett Creek drainages as part of the area limitation. The projected 2013 harvest for the herd unit is roughly 70 rams and 6-7 ewes. The 2013 post-season population estimate will again be around 1,400 sheep.

Management Evaluation

Current Postseason Population Management Objective: 200

2012 Postseason Population Estimate: ~180

2013 Proposed Postseason Population Estimate: ~180

Herd Unit Issues. Prior to the first transplant (1973) into the Devil’s Canyon area, a goal of 200 bighorn sheep was established. That population objective was carried over following the most recent transplants (2004, 2006). No population model/estimate has been developed for this small herd. The population objective is scheduled to be reviewed in 2014 and it is expected that the population will be near that level by then.

This herd unit is mostly public land (90%) managed by the BLM. The one landowner (family corporation) controls almost all access to areas occupied by bighorns. Anthropogenic factors have limited impacts on this population. Since access to this area is difficult, public use of the area is low. No human development (oil/gas, mining, housing) currently affect this population or their habitats. There is limited farming (irrigated pastures) on a small portion of private land. Bighorn are attracted to those pastures especially during drought years. The landowners have commented on the concentration of sheep on those pastures, but have not “complained”.

Weather. Climatic conditions probably have the most influence on productivity and survival of this population. In 2012, temperatures were above normal throughout the region and precipitation was 4-5 inches below normal at airport weather stations (Greybull, Worland). Precipitation closer to the Bighorn Mountains was somewhat higher than what accumulated near those towns, although no site-specific data was available. Drought also occurred in the Bighorn Basin between 2000-04.

Habitat. Drought may be affecting production of herbaceous vegetation and extended dry conditions may be impacting shrub production and survival. Cheatgrass has become established in the area and dominant on some sites.

Field Data. Although drought conditions were documented during summer 2012 across most of Wyoming, affects on this bighorn sheep herd appear to have been minimal. The lamb:ewe ratio observed in summer 2012 (59:100) was higher than in 2011 (48:100), thus drought probably did not impact lamb survival (birth to July). Hunters mentioned that the two harvested bighorn rams were in good body condition and bighorns observed in September appeared to be in good physical condition. Use of irrigated pastures may have negated negative effects of drought. During the 2012 pre-season survey, WGFD personnel observed a total of 17 rams (5 class I rams, 9 class II rams, 3 class III rams, and 0 class IV rams).

Harvest Data. Harvest statistics will also provide little information about trend of this population. Only one or two licenses have been issued since 2008 and hunter success has been 100% each year. Recreation days and days per harvested animal vary depending on amount of time each hunter was able to allocate to his/her hunt. Average age of harvested rams also does not indicate a trend since only 1-2 rams were harvested each year. It was believed that the ram harvested in 2010 was incorrectly aged (10 years) based upon the hunter's comments and count of annual rings on photos. Also, genetics of rams from the recent transplants allowed for more growth of those young rams. One ram from Missouri River breaks (Montana) was harvested as a 6-year old (scored >180).

Most hunters in this herd have commented favorably on their hunter experience. One hunter in 2012, however, was dissatisfied with the number and size of rams that they observed. She harvested an 8-year old ram.

Population. Insufficient data has been collected for building a population model, thus there is no reliable estimate of the number of bighorns in this population. Pre-season (summer) classification surveys have been conducted the past five years. That data has also been used to indicate population trend. This population is believed to be increasing.

Total number of sheep observed during classification surveys may give the most consistent estimate of the trend in the population (Fig. 1). However, some surveys were not conducted across all areas used by bighorns and effort (flight time, aerial vs. ground) has not been consistent across years. Less flight time was spent during the 2012 classification flight which resulted in fewer sheep being observed. During September 2012, 139 bighorn were observed during a ground survey, so it is evident the 2012 pre-season survey was incomplete. Aerial trend counts will continue as budgets allow.

Figure 1. Total number of bighorn sheep observed during pre-season classification surveys of the Devil's Canyon herd unit, 2007-2012.

Management Summary. In 2012, hunting season guidelines were drafted for this herd, but not officially adopted by the Department or Commission (Table 1). Guidelines were developed based upon harvest management plans from other states. Many states base the number of hunting licenses for a given year upon the number of mature rams ($\geq \frac{3}{4}$ curl) observed during the previous year's annual survey. Some states also include criteria for population size and ram:ewe ratios. As another management consideration, Montana Fish, Wildlife & Parks considers amount of time since a population was transplanted into a new area. They do not allow hunting until 10 (or more) years following transplant operations to allow the population to increase and stabilize. The Devil's Canyon herd was originally started in 1973 with supplemental transplants in 2004 and 2006. Two rams harvested within the past 2 hunting seasons (2011, 2012), were released into the area during 2004 and 2006 transplant efforts. It was hoped that transplanted sheep would increase the genetic diversity of this population. Removing those rams (6 years old and 9 years old) limited their contribution to the genetic makeup of this population. If transplanted rams represent the best "trophies" observed by hunters, we should be trying to limit hunting of transplanted rams until those trophy characteristics can be passed along to future generations. More licenses will mean more hunting pressure on those rams that were released into the population.

Table 1. Guidelines for managing hunting of rams in the Devil's Canyon bighorn sheep herd.

When the herd has:			Hunting season structure:	Number of Ram licenses is:
Population size	Rams:100 ewes	% of rams $\geq \frac{3}{4}$ curl		
> 10% below objective	< 40:100	< 30	Restrictive	Up to 10% of $\geq \frac{3}{4}$ curl rams
\pm 10% of objective	40-60:100	≥ 30	Standard	Up to 15% of $\geq \frac{3}{4}$ curl rams
> 10% above objective	>60:100	≥ 30	Liberal	Up to 20% of $\geq \frac{3}{4}$ curl rams

Using the above criteria and 2012 survey data (see above), the restrictive hunting season structure would be recommended; one license. Using data from the 2011 classification survey (143 total sheep, 59 rams:100 ewes, and 49% of rams were $\geq \frac{3}{4}$ curl), the standard season structure would be recommended (three licenses.)

The landowners that controls access to this area do not wish to deal with more than two bighorn sheep hunters each year. They feel that more hunters would result in conflicts between hunters since these rams are highly visible and apparently not "afraid" of human activity (too vulnerable). Relations with the landowner were strained at one point, so efforts are still being made to repair that relationship and compromise on license numbers. In keeping with the landowner's desires and using the 2012 survey data, we proposed two licenses for the 2013 hunting season (one resident, one nonresident).

As the population increases, the landowners will realize more benefits (access fee) and may want to control the population more to minimize use of irrigated pastures. At that time, more ram licenses could be issued. This herd will be used as source herd for future transplants to new areas to assist with population control.
